An algorithm for suffix stripping

M.F. Porter
Computer Laboratory, Corn Exchange Street, Cambridge

ABSTRACT

The automatic removal of suffixes from words in English is of particular interest in the field of information retrieval. An algorithm for suffix stripping is described, which has been implemented as a short, fast program in BCPL. Although simple, it performs slightly better than a much more elaborate system with which it has been compared. It effectively works by treating complex suffixes as compounds made up of simple suffixes, and removing the simple suffixes in a number of steps. In each step the removal of the suffix is made to depend upon the form of the remaining stem, which usually involves a measure of its syllable length.

1. INTRODUCTION

Removing suffixes from words by automatic means is an operation which is especially useful in the field of information retrieval. In a typical IR environment, one has a collection of documents, each described by the words in the document title and possibly the words in the document abstract. Ignoring the issue of precisely where the words originate, we can say that a document is represented by a vector of words, or terms. Terms with a common stem will usually have similar meanings, for example:

CONNECT
CONNECTED
CONNECTING
CONNECTION
CONNECTIONS

Frequently, the performance of an IR system will be improved if term groups such as this are conflated into a single term. This may be done by removal of the various suffixes -ED, -ING, -ION, -IONS to leave the single stem CONNECT. In addition, the suffix stripping process will reduce the total number of terms in the IR system, and hence reduce the size and complexity of the data in the system, which is always advantageous.

Many strategies for suffix stripping have been reported in the literature.\cite{1-4} The nature of the task will vary considerably depending on whether a stem dictionary is being used, whether a suffix list is being used, and of course on the purpose for which the suffix stripping is being done. Assuming that one is not making use of a stem dictionary, and that the purpose of the task is to improve IR performance, the suffix stripping program will usually be given an explicit list of suffixes, and, with each suffix, the criterion under which it may be removed from a word to leave a valid stem. This is the approach adopted here. The main merits of the present program are that it is small (less than 400 lines of BCPL), fast (it will process a vocabulary of 10,000 different words in about 8.1 seconds on the IBM 370/165 at Cambridge University), and reasonably simple. At any rate, it is simple enough to be described in full as an algorithm in this paper. (The present version in BCPL is freely available from the author. BCPL itself is available on a wide range of different computers, but anyone wishing to use the program should have little difficulty in coding it up in other programming languages.) Given the speed of the program, it would be quite realistic to apply it to every word in a large file of continuous text, although for historical reasons we have found it convenient to apply it only to relatively small vocabulary lists derived from continuous text files.

In any suffix stripping program for IR work, two points must be borne in mind. Firstly, the suffixes are being removed simply to improve IR performance, and not as a linguistic exercise. This means that it would not be at all obvious under what circumstances a suffix should be removed, even if we could exactly determine the suffixes of the words by automatic means.

Perhaps the best criterion for removing suffixes from two words $W_i$ and $W_j$ to produce a single stem $S$, is to say that we do so if there appears to be no difference between the two statements 'a document is about $W_i$' and 'a document is about $W_j$'. So if $W_i$ = 'CONNECTION' and $W_j$ = 'CONNECTIONS' it seems very reasonable to conflate them to a single stem. But if $W_i$ = 'RELATE' and $W_j$ = 'RELATIVITY' it seems perhaps unreasonable, especially if the document collection is concerned with theoretical physics. (It should perhaps be added that RELATE and RELATIVITY are conflated together in the algorithm described here.) Between these two extremes there is a continuum of different cases, and given two terms $W_i$ and $W_j$, there will be some variation in opinion as to whether they should be conflated, just as there is with deciding the relevance of some document to a query. The evaluation of the worth of a suffix stripping system is correspondingly difficult.

The second point is that with the approach adopted here, i.e. the use of a suffix list with various rules, the success rate for the suffix stripping will be significantly less than 100%, irrespective of how the process is evaluated. For example, if SAND and SANDER get conflated, so most probably will WAND and WANDER. The error here is that the ER of WANDER has been treated as a suffix when in fact it is part of the stem. Equally a suffix may completely alter the meaning of a word, in which case its removal is unhelpful. PROBE and PROBATE for example, have quite distinct meanings in modern English. (In fact these would not be conflated in our present algorithm.) There comes a stage in the development of a suffix stripping program where the addition of more rules to increase the performance in one area of the vocabulary causes an equal degradation of performance elsewhere. Unless this phenomenon is noticed in time, it is very easy for the program to become much more complex than is really necessary. It is also easy to give undue emphasis to cases which appear to
be important, but which turn out in practice to be rather rare. For example, cases in which the spelling of the root of the word changes with the addition of a suffix, as in DECEIVE/DECEPTION, RESUME/RESUMPTION, INDEX/INDICES, occur much more rarely in real vocabularies than one might at first suppose. In view of the error rate that must in any case be expected, it did not seem worthwhile to try and cope with these cases.

It is not obvious that the simplicity of the present program is any demerit. In a test on the well known Cranfield 200 collection it gave an improvement in retrieval performance when compared with a very much more elaborate program which has been in use in IR research at Cambridge since 1971\(^2\).\(^3\).

The test was done as follows: the words of the titles and abstracts in the documents were passed through the earlier suffix stripping system, and the resulting stems were used to index the documents. The words of the queries were reduced to stems in the same way, and the documents were ranked for each query using term coordination matching of query against document. From these rankings, recall and precision values were obtained using the standard recall cutoff method. The entire process was then repeated using the suffix stripping system described in this paper, and the results were as follows:

<table>
<thead>
<tr>
<th>Earlier System</th>
<th>Present System</th>
</tr>
</thead>
<tbody>
<tr>
<td>Precision</td>
<td>Recall</td>
</tr>
<tr>
<td>0</td>
<td>57.24</td>
</tr>
<tr>
<td>10</td>
<td>56.85</td>
</tr>
<tr>
<td>20</td>
<td>52.85</td>
</tr>
<tr>
<td>30</td>
<td>42.61</td>
</tr>
<tr>
<td>40</td>
<td>42.20</td>
</tr>
<tr>
<td>50</td>
<td>39.06</td>
</tr>
<tr>
<td>60</td>
<td>32.86</td>
</tr>
<tr>
<td>70</td>
<td>31.64</td>
</tr>
<tr>
<td>80</td>
<td>27.15</td>
</tr>
<tr>
<td>90</td>
<td>24.59</td>
</tr>
<tr>
<td>100</td>
<td>24.59</td>
</tr>
</tbody>
</table>

Clearly the performance is not very different. The important point is that the earlier, more elaborate system certainly performs no better than the present, simple system.

(This test was done by Prof. C.J. van Rijsbergen.)

2. THE ALGORITHM

To present the suffix stripping algorithm in its entirety we will need a few definitions.

A consonant in a word is a letter other than A, E, I, O and U, and other than Y preceded by a consonant. (The fact that the term ‘consonant’ is defined to some extent in terms of itself does not make it ambiguous.) So in TOY the consonants are T and Y, in SYZYGY they are S, Z and G. If a letter is not a consonant it is a vowel.

A consonant will be denoted by c, a vowel by v. A list ccc . . . of length greater than 0 will be denoted by C, and a list vvv . . . of length greater than 0 will be denoted by V. Any word, or part of a word, therefore has one of the four forms:

\[
\begin{align*}
&\text{CV} \text{CV} \ldots \text{C} \\
&\text{CV} \text{CV} \ldots \text{V} \\
&\text{VC} \text{VC} \ldots \text{C} \\
&\text{VC} \text{VC} \ldots \text{V}
\end{align*}
\]

These may all be represented by the single form

\[
\text{[C]} \text{VC} \text{VC} \ldots \text{[V]}
\]

where the square brackets denote arbitrary presence of their contents. Using \((\text{VC})^m\) to denote VC repeated m times, this may again be written as

\[
\text{[C]} \text{VC} \ldots \text{[V]}
\]

m will be called the measure of any word or word part when represented in this form. The case \(m=0\) covers the null word. Here are some examples:

\[
\begin{align*}
m=0 & & \text{TR, EE, TREE, Y, BY} \\
m=1 & & \text{TROUBLE, OATS, TREES, IVY} \\
m=2 & & \text{TROUBLES, PRIVATE, OATEN, ORRERY}
\end{align*}
\]

The rules for removing a suffix will be given in the form

\[
\text{(condition)} \ S_1 \rightarrow S_2
\]

This means that if a word ends with the suffix \(S_1\), and the stem before \(S_1\) satisfies the given condition, \(S_1\) is replaced by \(S_2\). The condition is usually given in terms of \(m\), e.g.

\[
(m>1) \ \text{EMENT} \rightarrow \\
\text{S}_1 \text{ is 'EMENT' and } S_2 \text{ is null. This would map REPLACEMENT to REPLAC, since REPLAC is word part for which } m=2.
\]

The ‘condition’ part may also contain the following:

\*
\*
\*

And the condition part may also contain expressions with and, or and not, so that

\[(m>1 \text{ and } S \text{ or } T)\]

tests for a stem with \(m>1\) ending in \(S\) or \(T\), while

\[(d \text{ and not } L \text{ or } S \text{ or } Z)\]

tests for a stem ending with a double consonant other than \(L, S\) or \(Z\). Elaborate conditions like this are required only very rarely.
In a set of rules written beneath each other, only one is obeyed, and this will be the one with the longest matching S1 for the given word. For example,

\[
\begin{align*}
\text{SSES} & \rightarrow \text{SS} \\
\text{IES} & \rightarrow \text{I} \\
\text{SS} & \rightarrow \text{SS} \\
\text{S} & \rightarrow
\end{align*}
\]

(here the conditions are all null) CARESSES maps to CARESS since SSES is the longest match for S1. Equally CARESS maps to CARESS (S1 = 'SS') and CARES to CARE (S1 = 'S').

In the rules below, examples of their application, successful or otherwise, are given on the right in lower case. The algorithm now follows:

**Step 1a**

<table>
<thead>
<tr>
<th>Rule</th>
<th>Example</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSES → SS</td>
<td>caresses → caress</td>
<td>ponies → poni</td>
</tr>
<tr>
<td>IES → I</td>
<td>ties → ti</td>
<td>caress → caress</td>
</tr>
<tr>
<td>SS → SS</td>
<td>cats → cat</td>
<td></td>
</tr>
</tbody>
</table>

**Step 1b**

(m > 0) EED → EE

<table>
<thead>
<tr>
<th>Rule</th>
<th>Example</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>feed → feed</td>
<td>agreed → agree</td>
<td>plastered → plaster</td>
</tr>
<tr>
<td>bled → bled</td>
<td>motoring → motor</td>
<td>sing → sing</td>
</tr>
</tbody>
</table>

(*v*) ED →

(*v*) ING →

If the second or third of the rules in Step 1b is successful, the following is done:

<table>
<thead>
<tr>
<th>Rule</th>
<th>Example</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>AT → ATE</td>
<td>conflat(ed) → conflate</td>
<td>troub(ling) → trouble</td>
</tr>
<tr>
<td>BL → BLE</td>
<td>siz(ed) → size</td>
<td>hopp(ing) → hop</td>
</tr>
<tr>
<td>IZ → IZE</td>
<td>tann(ed) → tan</td>
<td>fall(ing) → fall</td>
</tr>
<tr>
<td>(≠d and not (*L or *S or *Z)) single letter</td>
<td>hiss(ing) → hiss</td>
<td>fizz(ed) → fizz</td>
</tr>
<tr>
<td>(m=1 and *o) → E</td>
<td>fail(ing) → fail</td>
<td>flik(ed) → file</td>
</tr>
</tbody>
</table>

The rule to map to a single letter causes the removal of one of the double letter pair. The -E is put back on -AT, -BL and -IZ, so that the suffixes -ATE, -BLE and -IZE can be recognised later. This E may be removed in step 4.

**Step 1c**

(*v*) Y → I

<table>
<thead>
<tr>
<th>Example</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>happy → happi</td>
<td>sky → sky</td>
</tr>
</tbody>
</table>

**Step 2**

\[
\begin{align*}
(m > 0) \text{ATIONAL} & \rightarrow \text{ATE} \quad \text{relational} & \rightarrow \text{relate} \\
(m > 0) \text{TIONAL} & \rightarrow \text{TION} \quad \text{conditional} & \rightarrow \text{condition} \\
(m > 0) \text{ENC} & \rightarrow \text{ENCE} \quad \text{rational} & \rightarrow \text{ration} \\
(m > 0) \text{ANCE} & \rightarrow \text{ANCE} \quad \text{valenci} & \rightarrow \text{valence} \\
(m > 0) \text{IZER} & \rightarrow \text{IZE} \quad \text{hesitanc} & \rightarrow \text{hesitance} \\
(m > 0) \text{ABLE} & \rightarrow \text{ABLE} \quad \text{digitizer} & \rightarrow \text{digitize} \\
(m > 0) \text{ALLI} & \rightarrow \text{AL} \quad \text{confirmabili} & \rightarrow \text{conformable} \\
(m > 0) \text{ENTLI} & \rightarrow \text{ENT} \quad \text{radicalli} & \rightarrow \text{radical} \\
(m > 0) \text{ENT} & \rightarrow \text{E} \quad \text{differentli} & \rightarrow \text{different} \\
(m > 0) \text{VUSLI} & \rightarrow \text{OUS} \quad \text{vileli} & \rightarrow \text{vile} \\
(m > 0) \text{IZATION} & \rightarrow \text{IZE} \quad \text{analogously} & \rightarrow \text{analogous} \\
(m > 0) \text{ATION} & \rightarrow \text{ATE} \quad \text{vietnamization} & \rightarrow \text{vietnamez} \\
(m > 0) \text{ATOR} & \rightarrow \text{ATE} \quad \text{predication} & \rightarrow \text{predicate} \\
(m > 0) \text{ALISM} & \rightarrow \text{AL} \quad \text{operator} & \rightarrow \text{operate} \\
(m > 0) \text{IVENESS} & \rightarrow \text{IVE} \quad \text{feudalism} & \rightarrow \text{feudal} \\
(m > 0) \text{FULNESS} & \rightarrow \text{FUL} \quad \text{decisiveness} & \rightarrow \text{decisive} \\
(m > 0) \text{OUSNESS} & \rightarrow \text{OUS} \quad \text{hopfulness} & \rightarrow \text{hopeful} \\
(m > 0) \text{ALITI} & \rightarrow \text{AL} \quad \text{callousness} & \rightarrow \text{callous} \\
(m > 0) \text{IVITI} & \rightarrow \text{IVE} \quad \text{formaliti} & \rightarrow \text{formal} \\
(m > 0) \text{BILITI} & \rightarrow \text{BLE} \quad \text{sensibiliti} & \rightarrow \text{sensible} \\
\end{align*}
\]

The test for the string S1 can be made fast by doing a program switch on the penultimate letter of the word being tested. This gives a fairly even breakdown of the possible values of the string S1. It will be seen in fact that the S1-strings in step 2 are presented here in the alphabetical order of their penultimate letter. Similar techniques may be applied in the other steps.

**Step 3**

\[
\begin{align*}
(m > 0) \text{ICATE} & \rightarrow \text{IC} \quad \text{triplicate} & \rightarrow \text{triplic} \\
(m > 0) \text{ATIVE} & \rightarrow \text{AT} \quad \text{formative} & \rightarrow \text{form} \\
(m > 0) \text{ALIZE} & \rightarrow \text{AL} \quad \text{formalize} & \rightarrow \text{formal} \\
(m > 0) \text{ICITI} & \rightarrow \text{IC} \quad \text{electriciti} & \rightarrow \text{electric} \\
(m > 0) \text{ICAL} & \rightarrow \text{IC} \quad \text{electrical} & \rightarrow \text{electrical} \\
(m > 0) \text{FUL} & \rightarrow \text{F} \quad \text{hopeful} & \rightarrow \text{hope} \\
(m > 0) \text{NESS} & \rightarrow \text{ GOODness} & \rightarrow \text{good} \\
\end{align*}
\]

**Step 4**

\[
\begin{align*}
(m > 1) \text{AL} & \rightarrow \text{revival} & \rightarrow \text{reviv} \\
(m > 1) \text{ANCE} & \rightarrow \text{allowance} & \rightarrow \text{allow} \\
(m > 1) \text{ENCE} & \rightarrow \text{inference} & \rightarrow \text{infer} \\
(m > 1) \text{ER} & \rightarrow \text{airliner} & \rightarrow \text{airlin} \\
(m > 1) \text{IC} & \rightarrow \text{gyroscopic} & \rightarrow \text{gyroscop} \\
(m > 1) \text{ABLE} & \rightarrow \text{adjustable} & \rightarrow \text{adjust} \\
(m > 1) \text{IBLE} & \rightarrow \text{defensible} & \rightarrow \text{defens}
\end{align*}
\]
Complex suffixes are removed bit by bit in the different steps. Thus GENERALIZATIONS is stripped to GENERALIZATION (Step 1), then to GENERALIZE (Step 2), then to GENERAL (Step 3), and then to GENER (Step 4). OSCILLATORS is stripped to OSCILLATOR (Step 1), then to OSCILLATE (Step 2), then to OSCILL (Step 4), and then to OSCIL (Step 5). In a vocabulary of 10,000 words, the reduction in size of the stem was distributed among the steps as follows:

<table>
<thead>
<tr>
<th>Suffix stripping of a vocabulary of 10,000 words</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of words reduced in step 1:</td>
</tr>
<tr>
<td>2:</td>
</tr>
<tr>
<td>3:</td>
</tr>
<tr>
<td>4:</td>
</tr>
<tr>
<td>5:</td>
</tr>
<tr>
<td>Number of words not reduced:</td>
</tr>
</tbody>
</table>

The resulting vocabulary of stems contained 6370 distinct entries. Thus the suffix stripping process reduced the size of the vocabulary by about one third.

Abstract
We report on the results of a series of experiments with a prototype text retrieval system which uses relatively advanced natural language processing techniques in order to enhance the effectiveness of statistical document retrieval. In this paper we show that large-scale natural language processing (hundreds of millions of words and more) is not only required for a better retrieval, but it is also doable, given appropriate resources. In particular, we demonstrate that the use of syntactic compounds in the representation of database documents as well as in user queries, coupled with an appropriate term weighting strategy, can considerably improve the effectiveness of retrospective search. The experiments reported here were conducted on TIPSTER database in connection with the Text REtrieval Conference series (TREC).\(^1\)

1 Introduction
The task of information retrieval is to extract relevant documents from a large collection of documents in response to user queries. When the documents contain primarily unrestricted text (e.g., newspaper articles, legal documents, etc.) the relevance of a document is established through ‘full-text’ retrieval. This has been usually accomplished by identifying key terms in the documents (the process known as ‘indexing’) which could then be matched against terms in queries (Salton, 1989). The effectiveness of any such term-based approach is directly related to the accuracy with which a set of terms represents the content of a document, as well as how well it contrasts a given document with respect to other documents. In other words, we are looking for a representation \(R\) such that for any text items \(D_1\) and \(D_2\), \(R(D_1) = R(D_2)\) iff \(\text{meaning}(D_1) = \text{meaning}(D_2)\), at an appropriate level of abstraction (which may depend on the types and character of anticipated queries).

The simplest word-based representations of content are usually inadequate since single words are rarely specific enough for accurate discrimination, and their grouping is often accidental. A better method is to identify groups of words that create meaningful phrases, especially if these phrases denote important concepts in the database domain. For example, joint venture is an important term in the Wall Street Journal (WSJ henceforth) database, while neither joint nor venture are important by themselves. In fact, in a 800+ Mbytes database, both joint and venture would often be dropped from the list of terms by the system because their inverted document frequency (idf) weights were too low. In large databases comprising hundreds of thousands of documents the use of phrasal terms is not just desirable, it becomes necessary.

To illustrate this point let us consider TREC Topic 104, an information request from which a database search query is to be built. The reader may note various sections of this Topic, with <desc> corresponding to the user’s original request, further elaborated in <narr>, and <con> consisting of expert-assigned phrases denoting key concepts to be considered.

<op>
<num> Number: 104
<dom> Domain: Law and Government
<title> Topic: Catastrophic Health Insurance
<desc> Description:
Document will enumerate provisions of the U.S. Catastrophic Health Insurance Act of 1988, or the political/legal fallout from that legislation.
<narr> Narrative:
A relevant document will detail the content of the U.S. medicare act of 1988 which extended catastrophic illness benefits to the elderly, with particular attention to the financing scheme which led to a firestorm of protest and a Congressional retreat, or a relevant document will detail the political/legal consequences of the catastrophic health insurance imbroglio and subsequent efforts by Congress to provide similar coverages through a less-controversial mechanism.
<con> Concept(s):

\(^1\) See (Harman, 1993) for a detailed description of TREC.
and mutual information, as well as partial parsing techniques, are prone to high error rates (sometimes as high as 50%), turning out many unwanted associations. Therefore a good, fast parser is necessary, but it is by no means sufficient. While syntactic phrases are often better indicators of content than "statistical phrases" — where words are grouped solely on the basis of physical proximity, e.g., "college junior" is not the same as "junior college" — the creation of compound terms makes the term matching process more complex since in addition to the usual problems of synonymy and subsumption, one must deal with their structure (e.g., "college junior" is the same as "junior in college").

For all kinds of terms that can be assigned to the representation of a document, e.g., words, syntactic phrases, fixed phrases, and proper names, various levels of "regularization" are needed to assure that syntactic or lexical variations of input do not obscure underlying semantic uniformity. Without actually doing semantic analysis, this kind of normalization can be achieved through the following processes:

1. morphological stemming: e.g., retrieving is reduced to retrieve;
2. lexicon-based word normalization: e.g., retrieval is reduced to retrieve;
3. operator-argument representation of phrases: e.g., information retrieval, retrieving of information, and retrieve relevant information are all assigned the same representation, retrieve + information;
4. context-based term clustering into synonymy classes and subsumption hierarchies: e.g., takeover is a kind of acquisition (in business), and Fortran is a programming language.

Introduction of compound terms complicates the task of discovery of various semantic relationships among them. For example, the term natural language can often be considered to subsume any term denoting a specific human language, such as English. Therefore, a query containing the former may be expected to retrieve documents containing the latter. The same can be said about language and English, unless language is in fact a part of the compound term programming language in which case the association language = Fortran is appropriate. This is a problem because (a) it is a standard practice to include both simple and compound terms in document representation, and (b) term associations have thus far been computed primarily at word level (including fixed phrases) and therefore care

\[2\] All single words (except the stopwords such as articles or prepositions) are included in the query, including those making up the phrases.

\[3\] Including extra terms in documents changes the way other terms are weighted. This issue is discussed later in this paper.

\[4\] An alternative, but less efficient method is to generate all variants (lexical, syntactic, etc.) of words/phrases in the queries (Sparck-Jones & Tait, 1984).
must be taken when such associations are used in term matching. This may prove particularly troublesome for systems that attempt term clustering in order to create "meta-terms" to be used in document representation.

2 Overall Design

We have established the general architecture of an NLP-IR system, depicted schematically below, in which an advanced NLP module is inserted between the textual input (new documents, user queries) and the database search engine (in our case, NIST's PRISE system). This design has already shown some promise in producing a better performance than the base statistical system (Strzalkowski, 1993b). We would like to point out at the outset that this system is completely automated, including the statistical core, and the natural language processing components, and no human intervention or manual encoding is required.

One of the observations made during the course of TREC-2 was to note that removing low-quality terms from the queries is at least as important (and often more so) as adding synonyms and specializations. In some instances (e.g., routing runs) low-quality terms had to be removed (or inhibited) before similar terms could be added to the query or else the effect of query expansion was all but drowned out by the increased noise.

After the final query is constructed, the database search follows, and a ranked list of documents is returned. It should be noted that all the processing steps, those performed by the backbone system, and those performed by the natural language processing components, are fully automated, and no human intervention or manual encoding is required.

3 Fast Parsing with TTP Parser

TTP (Tagged Text Parser) is a full-grammar parser based on the Linguistic String Grammar developed by Sager (1981). It currently encompasses most of the grammar productions and many of the restrictions, but it is by no means complete. Unlike a conventional parser, TTP's output is a regularized representation of each sentence which reflects its logical predicate-argument structure, e.g., logical subject and logical objects are identified depending upon the main verb subcategorization frame. For example, the verb abide has, among others, a subcategorization frame in which the object is a prepositional phrase with by, as in he'll abide by the court's decision, i.e.,

ABIDE: subject NP object PREP by NP

Subcategorization information is read from the on-line Oxford Advanced Learner's Dictionary (OALD) which TTP uses.

Also unlike a conventional parser, TTP is equipped with a powerful skip-and-fit recovery mechanism that allows it to operate effectively in the face of ill-formed input or under severe time pressure. A built-in timer regulates the amount of time allowed for parsing any one sentence: if a parse is not returned before the allotted time elapses, TTP enters the skipping mode in which it will try to "fit" the parse. While in the skip-and-fit mode, the parser attempts to forcibly reduce incomplete constituents, possibly skimming over portions of input in order to restart parsing at a next unattempted constituent; in other words, it will favor reduction over backtracking. The result of this strategy is an approximate parse, partially fitted using top-down predictions. In runs with approximately 130 million words of TREC's Wall Street Journal and San Jose Mercury texts, the parser's speed averaged 30 minutes per Megabyte or about 80 words per second, on a Sun SparcStation10. In addition, TTP has been shown to produce parse structures which are no worse
than those generated by full-scale linguistic parsers when compared to hand-coded parse trees.5

Full details of TTP parser have been described in the TREC-1 report (Strzalkowski, 1993a), as well as in
other works (Strzalkowski, 1992; Strzalkowski &
Schevyn, 1993).

As may be expected, the skip-and-fit strategy will only be effective if the input skipping can be per-
formed with a degree of determinism. This means that
most of the lexical level ambiguity must be removed
from the input text, prior to parsing. We achieve this
using a stochastic part of speech tagger to preprocess
the text prior to parsing. In order to streamline the pro-
cessing, we also perform morphological normalization
of words on the tagged text, before parsing. This is pos-
able because the part-of-speech tags retain the informa-
tion about each word’s original form. Thus the sen-
tence The Soviets have been notified is transformed into
the/dt soviet/nps have/vbp be/verb vbn notify/vb before

5 Hand-coded parse trees were obtained from the University
of Pennsylvania Treebank Project database.

4 Head-Modifier Structures

Syntactic phrases extracted from TTP parse struc-
tures are represented as head-modifier pairs. The
head in such a pair is a central element of a phrase
(main verb, main noun, etc.), while the modifier is one
of the adjuncts or arguments of the head. In the TREC
experiments reported here we extracted head-modifier
word pairs only, i.e., nested pairs were not used even
though this was warranted by the size of the database.

Figure 1 shows all stages of the initial linguistic
analysis of a sample sentence from the WSJ database.
The reader may note that the parser’s output is a
predicate-argument structure centered around the main
elements of various phrases. For example, BE is the
main predicate (modified by HAVE) with 2 arguments
(subject, object) and 2 adjuncts (adv, sub ord).

... INVDAE is the predicate in the subordinate clause with
2 arguments (subject, object). The subject of BE is a
noun phrase with PRESIDENT as the head element,
two modifiers (FORMER, SOVIE) and a determiner
(THE). From this structure, we extract head-modifier
pairs that become candidates for compound terms.
In general, the following types of pairs are considered:
(1) a head noun of a noun phrase and its left adjective or
noun adjunct, (2) a head noun and the head of its right
adjunct, (3) the main verb of a clause and the head of
its object phrase, and (4) the head of the subject phrase

and the main verb. These types of pairs account for
most of the syntactic variants for relating two words (or
simple phrases) into pairs carrying compatible semantic
content. For example, the pair retrieve+information
will be extracted from any of the following fragments:
information retrieval system; retrieval of information
from databases; and information that can be retrieved
by a user-controlled interactive search process. We
also attempted to identify and remove any terms which
were explicitly negated in order to prevent matches
against their positive counterparts, either in the data-
base or in the queries.

One difficulty in obtaining head-modifier pairs of
highest accuracy is the notorious ambiguity of nominal
compounds. The pair extractor looks at the distribution
statistics of the compound terms to decide whether the
association between any two words (nouns and adjectives)
in a noun phrase is both syntactically valid and
semantically significant. For example, we may accept
language+natural and processing+language from

Figure 1. Stages of sentence processing.
natural language processing as correct, however, case+trading would make a mediocre term when extracted from insider trading case. On the other hand, it is important to extract trading+insider to be able to match documents containing phrases insider trading sanctions act or insider trading activity.

5 Term Weighting Issues

Finding a proper term weighting scheme is critical in term-based retrieval since the rank of a document is determined by the weights of the terms it shares with the query. One popular term weighting scheme, known as tf.idf, weights terms proportionately to their inverted document frequency scores and to their in-document frequencies (df). The in-document frequency factor is usually normalized by the document length, that is, it is more significant for a term to occur in a short 100-word abstract, than in a 5000-word article.7

A standard tf.idf weighting scheme (see Buckley, 1993 for details) may be inappropriate for mixed term sets, consisting of ordinary concepts, proper names, and phrases, because:

(1) It favors terms that occur fairly frequently in a document, which supports only general-type queries (e.g., "all you know about X"). Such queries were not typical in TREC.

(2) It attaches low weights to infrequent, highly specific terms, such as names and phrases, whose only occurrences in a document are often decisive for relevance. Note that such terms cannot be reliably distinguished using their distribution in the database as the sole factor, and therefore syntactic and lexical information is required.

(3) It does not address the problem of inter-term dependencies arising when phrasal terms and their component single-word terms are all included in a document representation, i.e., launch+satellite and satellite are not independent, and it is unclear whether they should be counted as two terms.

In our post-TREC-2 experiments we considered (1) and (2) only. We changed the weighting scheme so that the phrases (but not the names, which we did not distinguish in TREC-2) were more heavily weighted by their idf scores while the in-document frequency scores were replaced by logarithms multiplied by sufficiently large constants. In addition, the top N highest-idf matching terms (simple or compound) were counted more toward the document score than the remaining terms.

Schematically, these new weights for phrasal and highly specific terms are obtained using the following formula, while weights for most of the single-word terms remain unchanged:

\[ \text{weight}(T_i) = (C_1 \cdot \log(df) + C_2 \cdot \alpha(N,i)) \cdot \text{idf} \]

In the above, \( \alpha(N,i) \) is 1 for \( i<N \) and is 0 otherwise. The selection of a weighting formula was partly constrained by the fact that document-length-normalized tf weights were precomputed at the indexing stage and could not be altered without re-indexing of the entire database. The intuitive interpretation of the \( \alpha(N,i) \) factor is as follows. We restrict the maximum number of terms on which a query is permitted to match a document to N highest weight terms, where N can be the same for all queries or may vary from one query to another. Note that this is not the same as simply taking the N top terms from each query. Rather, for each document for which there are M matching terms with the query, only \( \min(M,N) \) of them, namely those which have highest weights, will be considered when computing the document score. Moreover, only the global importance weights for terms are considered (such as idf), while local in-document frequency (e.g., tf) is suppressed by either taking a log or replacing it with a constant.

Changing the weighting scheme for compound terms, along with other minor improvements (such as expanding the stopword list for topics, or correcting a few parsing bugs) has lead to an overall increase of precision of more than 20% over our official TREC-2 ad-hoc results. Table 1 includes statistics of these new runs for 50 queries (numbered 101-150) against the WSJ database. The gap between the precision levels in columns \( \text{txt2} \) and \( \text{con} \) reflects the difference in the quality of the queries obtained from the narrative parts of the topics (\( \text{txt2} = \text{title + desc + narr} \)), and those obtained primarily from expert's formulation (\( \text{title + desc + con} \)). The column \( \text{txt2+nlp} \) represents the improvement of \( \text{txt2} \) queries thanks to NLP, with as much as 70% of the gap closed. Similar improvements have been obtained for other sets of queries.

6 Conclusions

We presented in some detail our natural language information retrieval system consisting of an advanced NLP module and a 'pure' statistical core engine. While many problems remain to be resolved, including the question of adequacy of term-based representation of document content, we attempted to demonstrate that the architecture described here is nonetheless viable. In particular, we demonstrated that natural language

---

7 This is not always true, for example when all occurrences of a term are concentrated in a single section or a paragraph rather than spread around the article.

Table 1. Run statistics for 50 ad-hoc queries against WSI database with 1000 docs retrieved per query: (1) txt1 - single terms of <narr> and <desc> fields - this is the base run; (2) txt2 - <narr> and <desc> fields with low weight terms removed; (3) txt2+nlp - <narr> and <desc> fields including syntactic phrase terms using the new weighting scheme; (4) con - <desc> and <con> fields with low weight terms removed but with no NLP; and (5) con+nlp - <desc> and <con> fields including phrases with the new weighting scheme.

processing can now be done on a fairly large scale and that its speed and robustness can match those of traditional statistical programs such as key-word indexing or statistical phrase extraction. We suggest, with some caution until more experiments are run, that natural language processing can be very effective in creating appropriate search queries out of a user’s initial specifications, which can be frequently imprecise or vague.
